NCCN Guidelines Version 2.2025

Occult Primary

Updates in Version 2.2025 of the NCCN Guidelines for Occult Primary from Version 1.2025 include:

[MS-1](#)

- The discussion section has been updated to reflect the changes in the algorithm.

Updates in Version 1.2025 of the NCCN Guidelines for Occult Primary from Version 2.2024 include:

[Global](#)

- References updated throughout document.

[OCC-1](#)

- Initial evaluation, bullet 1: Complete H&P, including breast, genitourinary, pelvic, ~~and~~ rectal, *skin, and/or oral cavity exam as appropriate*, with attention to...
- Workup:
 - ▶ Bullet removed: Gene sequencing to predict tissue of origin is not recommended.
 - ▶ Bullet added: Tissue of origin studies are not recommended.

[OCC-1A](#)

- Footnote d, references added.

[OCC-3](#)

- Header added: Histologic Diagnosis. (also for OCC-4, OCC-5, OCC-6, OCC-8, OCC-9, OCC-10, OCC-11, OCC-13, and OCC-14)
- Footnote k modified: Symptom-directed endoscopy, ~~such as endoscopy~~, can be considered... (also for OCC-4, OCC-5, OCC-6, and OCC-11)

[OCC-8](#)

- Mediastinum algorithm text removed:
 - ▶ Consider additional consultation with pathologist to determine if further analysis would be helpful.

[OCC-11](#)

- Supraclavicular nodes, additional workup, bullet added: Endoscopy as indicated.

[OCC-A \(1 of 5\)](#)

- Header modified: Potential Immunohistochemistry/*In Situ Hybridization* Markers for Unknown Primary Cancers
- Subheading modified: *Communication between the clinician and the pathologist is essential for the workup to direct the staining pattern to the clinical differential diagnosis. The pathologist should select a focused panel of IHC or ISH markers, and avoid a large series of markers. IHC and ISH markers for unknown primary cancers are provided as a resource to assist in localizing a primary but are not uniformly specific or sensitive. Avoid a large series of immunohistochemistry markers. Communication with the pathologist is essential to workup.*

[OCC-A \(4 of 5\)](#)

- Neuroendocrine carcinoma, other positive markers: CD56 removed.

[OCC-B \(all\)](#)

- Pages extensively revised.

[OCC-B \(2 of 14\)](#)

- Repotrectinib added as a Useful in Certain Circumstances regimen for NTRK gene fusion-positive tumors. (Also for OCC-B [8 of 14])

[OCC-C](#)

- General principles, dosing regimen modified: (48-60 Gy *†*in 4–5 fractions).

NCCN Guidelines Version 2.2025

Occult Primary

INITIAL EVALUATION^b

WORKUP

PATHOLOGIC DIAGNOSIS

Suspected
metastatic
malignancy^a

- Complete history and physical (H&P), including breast, genitourinary, pelvic, rectal, skin, and/or oral cavity exam as appropriate, with attention to and review of:
- Past biopsies or malignancies
- Removed lesions
- Spontaneously regressing lesions
- Existing imaging studies
- Calcium
- Complete blood count (CBC)
- Creatinine
- Electrolytes
- Hemoccult test as indicated
- Lactate dehydrogenase (LDH) as indicated
- Liver function tests (LFTs)
- Urinalysis as indicated
- Chest/abdomen/pelvis CT^c scan
- Clinically directed endoscopy, as indicated

- Biopsy^d:**
- Core needle biopsy (preferred) and/or fine-needle aspiration (FNA) with cell block of most accessible site
 - Consult pathologist for adequacy of specimen and additional studies including immunohistochemical (IHC) stains^e
 - Tumor mutational burden (TMB) determination by a validated and/or FDA-approved assay (category 2B)^f
 - Microsatellite instability (MSI)/mismatch repair (MMR) testing^g
 - Molecular profiling of tumor tissue using next-generation sequencing (NGS) (or other technique to identify gene fusions) can be considered after an initial determination of histology has been made^h
 - Tissue of origin studies are not recommendedⁱ

- Epithelial; not site specific or poorly differentiated neoplasm → Clinical Presentation ([OCC-2](#))
- Lymphoma and other hematologic malignancies → See [NCCN Guidelines Treatment by Cancer Type](#)
- Thyroid carcinoma → See [NCCN Guidelines for Thyroid Carcinoma](#)
- Melanoma → See [NCCN Guidelines for Melanoma: Cutaneous](#)
- Sarcoma → See [NCCN Guidelines for Soft Tissue Sarcoma](#)
- Germ cell tumor → See [NCCN Guidelines for Testicular Cancer](#)
- Nonmalignant diagnosis → Further evaluation and Appropriate follow-up

Note: All recommendations are category 2A unless otherwise indicated.

[Footnotes on OCC-1A](#)

FOOTNOTES

- ^a For many patients the apparent uncertainties surrounding the diagnosis of an unknown primary cancer may result in significant psychosocial distress and increased difficulty in accepting treatment options. Empathetic discussion about the natural history of these types of cancer and their prognosis, and the provision of support and counseling both by the primary oncology team and specialized services may help to alleviate this distress. See [NCCN Guidelines for Distress Management](#).
- ^b Testing for some tumor markers such as serum CA-125, CA 19-9, and CA 15-3 may be useful in certain circumstances, but are not diagnostic and caution must be exercised in their interpretation.
- ^c CT should be performed with contrast and MRI should be performed with and without IV contrast unless contraindicated. FDG-PET/CT is an alternative in patients with a contraindication to contrast enhancement.
- ^d If available, the pathologist should be involved with the biopsy to provide rapid on-site evaluation (ROSE) to confirm adequate sampling of the lesion and to perform specimen triage including cell block with immediate formalin fixation, flow cytometry, and other ancillary studies as needed. Sauter JL, et al. J Am Soc Cytopathol 2020;9:570-578; VanderLaan PA, et al. J Am Soc Cytopathol 2019;8:333-341.
- ^e [Immunohistochemistry/In Situ Hybridization Markers for Unknown Primary Cancers \(OCC-A\)](#).
- ^f Merino DM, et al. J Immunother Cancer 2020;8:e000147.
- ^g The population of patients with MSI-high/MMR-deficient (MSI-H/dMMR) occult primary tumors is low. Use IHC for MMR or polymerase chain reaction (PCR) for MSI, which are different assays measuring the same biological effect.
- ^h Consider tumor/somatic molecular profiling for patients who are candidates for anti-cancer therapy to identify uncommon mutations (ie, *RET* fusions). Testing on tumor tissue is preferred; however, cell-free DNA testing can be considered if tumor tissue testing is not feasible.
- ⁱ Hayashi H, et al. J Clin Oncol 2019;37:570-579.

Note: All recommendations are category 2A unless otherwise indicated.

Follow-up ([OCC-15](#))

FOLLOW-UP FOR ALL OCCULT PRIMARIES (NO ACTIVE TREATMENT)

- For patients with active disease or disease in remission, follow-up frequency should be determined by clinical need.
 - H&P
 - Diagnostic tests based on symptomatology
- For patients with active and incurable disease, psychosocial support, symptom management, end-of-life discussions, palliative care interventions, and hospice care should all be considered and utilized as appropriate.
- See [NCCN Guidelines for Palliative Care](#), [NCCN Guidelines for Distress Management](#), and [NCCN Guidelines for Survivorship](#).

Note: All recommendations are category 2A unless otherwise indicated.

POTENTIAL IMMUNOHISTOCHEMISTRY/IN SITU HYBRIDIZATION MARKERS FOR UNKNOWN PRIMARY CANCERS

Communication between the clinician and the pathologist is essential for the workup to direct the staining pattern to the clinical differential diagnosis. The pathologist should select a focused panel of IHC or ISH markers, and avoid a large series of markers. IHC and ISH markers for unknown primary cancers are provided as a resource to assist in localizing a primary but are not uniformly specific or sensitive.

TUMOR-SPECIFIC MARKERS AND THEIR STAINING PATTERN^{1,2}

<u>Marker</u>	<u>Tumor</u>	<u>Staining Pattern</u>
Arginase-1	Hepatocellular	Nuclear/cytoplasmic
Calretinin	Mesothelioma, sex cord–stromal, adrenocortical	Nuclear/cytoplasmic
CDX2	Colorectal, other gastrointestinal, pancreaticobiliary tract	Nuclear
D2-40	Mesothelioma, lymphatic endothelial cell marker	Membranous
EBV	Nasopharynx	Nuclear
ER/PR	Breast, ovary, endometrium	Nuclear
GATA3	Breast, urinary bladder, salivary gland	Nuclear
Glypican-3	Hepatocellular	Cytoplasmic
HepPar-1	Hepatocellular	Cytoplasmic
HPV	Cervix, vulva, vagina, penis, anal, oropharynx	Nuclear (DNA ISH); nuclear/cytoplasmic (RNA ISH)
Inhibin	Sex cord–stromal, adrenocortical	Cytoplasmic
Melan-A	Adrenocortical, melanoma	Nuclear
Napsin A	Lung	Cytoplasmic
NKX3-1	Prostate	Nuclear
PAP	Prostate	Membranous
PAX8	Thyroid, renal, ovary, endometrium, cervix, thymus	Nuclear
PSA	Prostate	Cytoplasmic
RCC marker	Renal	Membranous
SF-1	Adrenocortical, sex–cord stromal	Nuclear
SATB2	Colorectal, osteosarcoma, and other gastrointestinal tract	Nuclear
Thyroglobulin	Thyroid	Cytoplasmic
TTF-1	Lung, thyroid	Nuclear
Uroplakin III	Urothelial	Membranous
Villin	Gastrointestinal (epithelia with brush border)	Apical
WT1	Ovarian serous, mesothelioma, Wilms	Nuclear

¹ ER/PR, estrogen receptor/progesterone receptor; gross cystic disease fluid protein 15; HepPar-1, hepatocyte paraffin 1; PAP, prostatic acid phosphatase; PSA, prostate-specific antigen; RCC, renal cell carcinoma; SF-1, steroidogenic factor-1; TTF-1, thyroid transcription factor 1. Reprinted from Bahrami A, Truong LD, Ro JY. Undifferentiated tumor: true identity by immunohistochemistry. Arch Pathol Lab Med 2008;132:326-348 with permission from Archives of Pathology & Laboratory Medicine. Copyright 2008 College of American Pathologists.

² Per physician discretion, TRK protein testing can be considered as part of broad immunohistochemistry testing (a positive test should then be confirmed with NGS). Drilon A, Laetsch TW, Kummar S, et al. Efficacy of larotrectinib in TRK fusion-positive cancers in adults and children. N Engl J Med 2018;378:731-739; Doebele RC, Drilon A, Paz-Ares L, et al. Entrectinib in patients with advanced or metastatic NTRK fusion-positive solid tumours: integrated analysis of three phase 1-2 trials. Lancet Oncol 2020;21:271-282.

Note: All recommendations are category 2A unless otherwise indicated.

POTENTIAL IMMUNOHISTOCHEMISTRY/IN SITU HYBRIDIZATION MARKERS FOR UNKNOWN PRIMARY CANCERS **Undifferentiated Panel: For Determining Most Likely Cell Lineage³**

Markers*	Most Likely Cell Lineage
Pan-keratin (AE1/AE3 & CAM5.2)	Carcinoma
CK5/6, p63/p40	Squamous cell carcinoma
S100, SOX10	Melanoma and sarcoma
LCA± CD20± CD3±	Lymphoma
OCT3/4± SALL4±	Germ cell tumor
WT1, calretinin, mesothelin, D2-40	Mesothelial tumor

***These markers are not uniformly specific or sensitive and can be present on other tumors.**

Note: All recommendations are category 2A unless otherwise indicated.

NCCN Guidelines Version 2.2025

Occult Primary

PRINCIPLES OF SYSTEMIC THERAPY

- Consider systemic therapy in symptomatic patients (PS 1–2) or asymptomatic patients (PS 0) with an aggressive cancer.
- Base the systemic therapy regimen (listed on the following pages and others) to be used on the histologic cancer type.

Neuroendocrine Tumors

For poorly differentiated (high-grade or anaplastic) or small cell subtype, see [NCCN Guidelines for Small Cell Lung Cancer](#)

For well-differentiated neuroendocrine tumors, see [NCCN Guidelines for Neuroendocrine and Adrenal Tumors](#) - Carcinoid Tumors

Note: All recommendations are category 2A unless otherwise indicated.

PRINCIPLES OF SYSTEMIC THERAPY

Selected Systemic Therapy for Occult Primaries: Adenocarcinoma^a

Regimens are listed in alphabetical order by category of preference.

Preferred Regimens	Other Recommended Regimens	Useful in Certain Circumstances
<ul style="list-style-type: none"> • Carboplatin and paclitaxel^{1,2} • Cisplatin and gemcitabine³ <p>Preferred Regimens for Presumed GI Primary Site</p> <ul style="list-style-type: none"> • CapeOX⁴ • FOLFIRI^{b,5-9} • mFOLFOX6^{b,4,10} 	<ul style="list-style-type: none"> • Capecitabine^{c,d,11,12} • Docetaxel and carboplatin¹³ • Docetaxel and cisplatin¹⁴ • Fluorouracil^{b,c,d,15-18} • Gemcitabine and carboplatin¹⁹ • Gemcitabine and docetaxel²⁰ • Irinotecan and carboplatin²¹ 	<p>Biomarker-Driven Therapy</p> <p>BRAF V600E mutation-positive tumors</p> <ul style="list-style-type: none"> • Dabrafenib + trametinib^{e,22} <p>dMMR/MSI-H tumors</p> <ul style="list-style-type: none"> • Dostarlimab-gxly^{f,9,23} • Pembrolizumab^{f,24-26} <p>NTRK gene fusion-positive tumors</p> <ul style="list-style-type: none"> • Entrectinib^{h,27} • Larotrectinib^{h,28} • Repotrectinib^{h,29} <p>TMB-high (TMB-H) (≥10 mut/Mb) tumors</p> <ul style="list-style-type: none"> • Pembrolizumab^{f,24-26,30} <p>HER2-positive (IHC 3+) tumors</p> <ul style="list-style-type: none"> • Fam-trastuzumab deruxtecan-nxki^{i,31} <p>RET gene fusion-positive tumors</p> <ul style="list-style-type: none"> • Selpercatinib^{j,32} <p>Cytotoxic Chemotherapy</p> <ul style="list-style-type: none"> • FOLFIRINOX^{b,c,k,33} • Irinotecan and gemcitabine^{l,34} • mFOLFIRINOX^{b,c,k,35,36} • Paclitaxel, carboplatin, and etoposide^{k,37}

^a Consider programmed death ligand 1 (PD-L1) testing for patients with recurrent, progressive, or metastatic disease.

^b Leucovorin is indicated with certain fluorouracil-based regimens. Depending on availability, these regimens may be used with or without leucovorin.

^c For patients with presumed gastrointestinal (GI) primary site.

^d These regimens can be given with concurrent radiation.

^e For patients with *BRAF* V600E mutation-positive unresectable or metastatic solid tumors that have progressed following prior treatment and have no satisfactory alternative treatment options.

^f [NCCN Guidelines for Management of Immunotherapy-Related Toxicities](#).

^g For patients with recurrent or advanced tumors that have progressed on or following prior treatment and who have no satisfactory alternative treatment options. Note, patients who had received prior immune checkpoint inhibitor therapy were excluded from the dostarlimab-gxly clinical trial.

^h For patients with *NTRK* gene fusion-positive tumors without a known acquired resistance mutation, that are metastatic or where surgical resection is likely to result in severe morbidity, and that have no satisfactory alternative treatments or that have progressed following treatment.

ⁱ For patients with advanced or metastatic solid tumors that progressed on or following prior systemic treatment and who have no satisfactory alternative treatment options.

^j For patients with advanced or metastatic solid tumors that progressed on or following prior systemic treatment or who have no satisfactory alternative treatment options.

^k Only for patients with PS ECOG 0–1.

^l For patients ineligible to receive platinum-based chemotherapy.

For Squamous Cell Carcinoma see [OCC-B 8 of 14](#)

PRINCIPLES OF SYSTEMIC THERAPY

DOSING SCHEDULES FOR OCCULT PRIMARIES: ADENOCARCINOMA

Preferred Regimens

Carboplatin and paclitaxel

Paclitaxel 175–200 mg/m² IV Day 1

Carboplatin AUC 5–6 IV Day 1

Repeat every 3 weeks¹

OR

Paclitaxel 80 mg/m² IV Days 1, 8, and 15

Carboplatin AUC 2 IV Days 1, 8, and 15

Repeat every 4 weeks²

Cisplatin and gemcitabine

Gemcitabine 1000–1250 mg/m² IV Days 1 and 8

Cisplatin 75 mg/m² IV Day 1

Repeat every 3 weeks³

Preferred Regimens for Presumed GI Primary Site

CapeOX

Oxaliplatin 130 mg/m² IV Day 1

Capecitabine 850–1000 mg/m² PO twice daily Days 1–14

Repeat every 3 weeks⁴

FOLFIRI^b

Irinotecan 180 mg/m² IV Day 1

Leucovorin 400 mg/m² IV infusion to match duration of irinotecan infusion Day 1

Fluorouracil 400 mg/m² IV bolus Day 1, then

Fluorouracil 1200 mg/m²/day IV continuous infusion x 2 days
(total 2400 mg/m² over 46–48 hours)

Repeat every 2 weeks^{5–9}

mFOLFOX6^b

Oxaliplatin 85 mg/m² IV Day 1

Leucovorin 400 mg/m² IV Day 1

Fluorouracil 400 mg/m² IV bolus Day 1, then

Fluorouracil 1200 mg/m²/day IV continuous infusion x 2 days
(total 2400 mg/m² over 46–48 hours)

Repeat every 2 weeks^{4,10}

^b Leucovorin is indicated with certain fluorouracil-based regimens. Depending on availability, these regimens may be used with or without leucovorin.

Note: All recommendations are category 2A unless otherwise indicated.

PRINCIPLES OF SYSTEMIC THERAPY

DOSING SCHEDULES FOR OCCULT PRIMARIES: ADENOCARCINOMA

Other Recommended Regimens

Capecitabine^c

Capecitabine 850–1250 mg/m² PO twice daily Days 1–14
Repeat every 3 weeks¹¹

Docetaxel and carboplatin

Docetaxel 65 mg/m² IV Day 1
Carboplatin AUC 5–6 IV Day 1
Repeat every 3 weeks¹³

Docetaxel and cisplatin

Docetaxel 60–75 mg/m² IV Day 1
Cisplatin 75 mg/m² IV Day 1
Repeat every 3 weeks¹⁴

Gemcitabine and carboplatin

Gemcitabine 1000 mg/m² IV Days 1 and 8
Carboplatin AUC 5 IV Day 8
Repeat every 3 weeks¹⁹

Gemcitabine and docetaxel

Gemcitabine 1000 mg/m² IV Days 1 and 8
Docetaxel 75 mg/m² IV Day 8
Repeat every 3 weeks²⁰

Irinotecan and carboplatin

Irinotecan 60 mg/m² IV Days 1, 8, and 15
Carboplatin AUC 5–6 IV Day 1
Repeat every 4 weeks²¹

Bolus or infusional fluorouracil^c/leucovorin^b Roswell Park regimen

Leucovorin 500 mg/m² IV Days 1, 8, 15, 22, 29, and 36
Fluorouracil 500 mg/m² IV bolus 1 hour after start of leucovorin
Days 1, 8, 15, 22, 29, and 36
Repeat every 8 weeks¹⁵

Simplified biweekly infusional fluorouracil^c/leucovorin^b (sLV5FU2)

Leucovorin 400 mg/m² IV Day 1, followed by
Fluorouracil 400 mg/m² IV bolus, then
Fluorouracil 1200 mg/m²/day IV continuous infusion x 2 days
(total 2400 mg/m² over 46–48 hours)
Repeat every 2 weeks¹⁶

Weekly fluorouracil^c and leucovorin^b regimens

Leucovorin 20 mg/m² IV Day 1,
Fluorouracil 500 mg/m² IV bolus injection 1 hour after the start of
leucovorin
Repeat every week¹⁷
OR
Fluorouracil 2600 mg/m² by 24-hour infusion plus leucovorin
500 mg/m² IV Day 1
Repeat every week¹⁷

^b Leucovorin is indicated with certain fluorouracil-based regimens. Depending on availability, these regimens may be used with or without leucovorin.

^c For patients with presumed GI primary site.

Note: All recommendations are category 2A unless otherwise indicated.

RET Gene Fusion-Positive Tumors

Selpercatinib^j

<50 kg: 120 mg PO twice daily³²

≥50 kg: 160 mg PO twice daily³²

^e For patients with *BRAF* V600E mutation-positive unresectable or metastatic solid tumors that have progressed following prior treatment and have no satisfactory alternative treatment options.

^f [NCCN Guidelines for Management of Immunotherapy-Related Toxicities](#).

^h For patients with *NTRK* gene fusion-positive tumors without a known acquired resistance mutation, that are metastatic or where surgical resection is likely to result in severe morbidity, and that have no satisfactory alternative treatments or that have progressed following treatment.

ⁱ For patients with advanced or metastatic solid tumors that progressed on or following prior systemic treatment and who have no satisfactory alternative treatment options.

^j For patients with locally advanced or metastatic solid tumors that progressed on or following prior systemic treatment or who have no satisfactory alternative treatment options.

Note: All recommendations are category 2A unless otherwise indicated.

PRINCIPLES OF RADIATION THERAPY

General Principles

- Consider definitive radiotherapy for patients with active disease.
 - ▶ Dosing regimen: Consider SBRT/SABR¹ for limited (1–3)² metastases and pulmonary metastases (48–60 Gy in 4–5 fractions).

Adjuvant Therapy

- Consider adjuvant RT after lymph node dissection if the disease is limited to a single nodal site with extranodal extension or inadequate nodal dissection with multiple positive nodes.
 - ▶ Dosing regimen: 45 Gy is recommended with or without boost of 5–9 Gy/1.8–2.0 Gy fraction to nodal basin for isolated supraclavicular, axillary, or inguinal nodal metastasis.

Palliative Therapy

- Consider palliative radiotherapy for symptomatic patients.
 - ▶ Hypofractionated RT can be used as palliative treatment for uncontrolled pain, impending pathologic fracture, or impending cord compression.
 - ▶ Dosing regimen: A number of hypofractionation regimens can be considered, but typically 8 Gy in 1 fraction, 20 Gy in 4–5 fractions, or 30 Gy in 10 fractions are most frequently used.

NCCN Guidelines Version 2.2025

Occult Primary

NCCN Categories of Evidence and Consensus

Category 1	Based upon high-level evidence (≥1 randomized phase 3 trials or high-quality, robust meta-analyses), there is uniform NCCN consensus (≥85% support of the Panel) that the intervention is appropriate.
Category 2A	Based upon lower-level evidence, there is uniform NCCN consensus (≥85% support of the Panel) that the intervention is appropriate.
Category 2B	Based upon lower-level evidence, there is NCCN consensus (≥50%, but <85% support of the Panel) that the intervention is appropriate.
Category 3	Based upon any level of evidence, there is major NCCN disagreement that the intervention is appropriate.

All recommendations are category 2A unless otherwise indicated.

NCCN Categories of Preference

Preferred intervention	Interventions that are based on superior efficacy, safety, and evidence; and, when appropriate, affordability.
Other recommended intervention	Other interventions that may be somewhat less efficacious, more toxic, or based on less mature data; or significantly less affordable for similar outcomes.
Useful in certain circumstances	Other interventions that may be used for selected patient populations (defined with recommendation).

All recommendations are considered appropriate.

Note: All recommendations are category 2A unless otherwise indicated.

NCCN Guidelines Version 2.2025

Occult Primary

Overview

Occult primary tumors, or cancers of unknown primary (CUPs), are histologically confirmed metastatic tumors whose primary site cannot be identified during standard pretreatment evaluation.^{1,2} These heterogeneous tumors have a wide variety of clinical presentations and a poor prognosis in most patients. Early dissemination, aggressiveness, and unpredictability of metastatic pattern are characteristic of these tumors.³ Median survival is 8 to 12 months and depends on several prognostic factors that are discussed below.² Select patients with favorable subsets of CUP have median overall survival (OS) in the range of 12 to 36 months.^{4,5}

These guidelines provide recommendations for evaluation, workup, management, and follow-up of two pathologic diagnoses in patients with epithelial occult primary cancer:

- Adenocarcinoma, or carcinoma not otherwise specified
- Squamous cell carcinoma (SCC)

Recommendations for neuroendocrine tumors or head and neck tumors of unknown primary origin can be found in the [NCCN Guidelines for Neuroendocrine and Adrenal Tumors](#) and the [NCCN Guidelines for Head and Neck Cancers](#), respectively.

The NCCN Clinical Practice Guidelines in Oncology (NCCN Guidelines®) for Occult Primary suggest diagnostic tests based on the location of disease and histology. For SCC, the guidelines focus on the most common sites of clinical presentation, namely the head and neck nodes, supraclavicular nodes, axillary nodes, inguinal nodes, and bone. For adenocarcinoma, 12 different clinical presentations are addressed, with suggested diagnostic tests for each location. For each of the pathologic diagnoses, if a primary tumor is subsequently found, treatment should be based on recommendations in the NCCN Clinical Practice Guidelines for

the cancer site corresponding to the primary tumor (see the list of [NCCN Guidelines for Treatment by Cancer Type](#)).

The management portion of the algorithm focuses on treatment of disseminated or localized disease for adenocarcinoma and site-specific SCC. The Panel endorses enrollment of patients in appropriate clinical trials when possible. In most patients with CUP, systemic therapy is palliative and does not significantly improve long-term survival. In patients with disseminated disease in particular, the treatment goals are directed toward symptom control and providing the best quality of life possible. However, certain clinical presentations of these tumors are associated with a better prognosis.⁶ Special pathologic studies can identify subsets of patients with tumor types that are more responsive to systemic therapy. Treatment options should be individualized for this selected group of patients to achieve optimal response and survival rates.

Literature Search Criteria and Guidelines Update Methodology

Prior to the update of this version of the NCCN Guidelines® for Occult Primary (Cancer of Unknown Primary [CUP]), an electronic search of the PubMed database was performed to obtain key literature using the following search terms: occult primary cancer; cancer of unknown primary; carcinoma of unknown primary; and cancer of unknown origin. The PubMed database was chosen as it remains the most widely used resource for medical literature and indexes peer-reviewed biomedical literature.⁷

The search results were narrowed by selecting studies in humans published in English. Results were confined to the following article types: Clinical Trial, Phase II; Clinical Trial, Phase III; Clinical Trial, Phase IV; Guideline; Practice Guideline; Randomized Controlled Trial; Meta-Analysis; Systematic Reviews; and Validation Studies.

NCCN Guidelines Version 2.2025

Occult Primary

The data from key PubMed articles as well as articles from additional sources deemed as relevant to these guidelines and discussed by the Panel have been included in this version of the Discussion section (eg, e-publications ahead of print, meeting abstracts). Recommendations for which high-level evidence is lacking are based on the Panel's review of lower-level evidence and expert opinion.

NCCN recommendations have been developed to be inclusive of individuals of all sexual and gender identities to the greatest extent possible. When citing published studies and recommendations from other organizations, the terms used (eg, *male*, *female*) reflect the cited sources.

The complete details of the development and update of the NCCN Guidelines are available at www.NCCN.org.

Sensitive/Inclusive Language Usage

NCCN Guidelines strive to use language that advances the goals of equity, inclusion, and representation. NCCN Guidelines endeavor to use language that is person-first; not stigmatizing; anti-racist, anti-classist, anti-misogynist, anti-ageist, anti-ableist, and anti-weight-biased; and inclusive of individuals of all sexual orientations and gender identities. NCCN Guidelines incorporate non-gendered language, instead focusing on organ-specific recommendations. This language is both more accurate and more inclusive and can help fully address the needs of individuals of all sexual orientations and gender identities. NCCN Guidelines will continue to use the terms *men*, *women*, *female*, and *male* when citing statistics, recommendations, or data from organizations or sources that do not use inclusive terms. Most studies do not report how sex and gender data are collected and use these terms interchangeably or inconsistently. If sources do not differentiate gender from sex assigned at birth or organs present, the information is presumed to predominantly represent cisgender individuals. NCCN encourages researchers to collect more specific data in

future studies and organizations to use more inclusive and accurate language in their future analyses.

Epidemiology

CUP has an average age at diagnosis of 60 to 75 years and accounts for 2% to 9% of all tumors.^{2,8} CUP is among the 10 most frequently diagnosed tumors in developed countries.^{2,9} An estimated 34,950 cases of CUP are expected to be diagnosed in the United States in 2024, accounting for approximately 2% of all U.S. cancers.¹⁰ However, deaths from CUP are estimated to reach 49,240 in 2024. This discrepancy is believed to reflect a lack of specificity in recording the underlying cause of death on death certificates and/or an undercount in the case estimate. Recently, the incidence of CUP diagnoses has been decreasing, which is likely attributed to improved diagnostics and detection of primary tumors.¹¹ Unfortunately, no improvement in median survival was seen over this time period.

A study based on an analysis of the Swedish Family-Cancer Database revealed that CUP may have a genetic basis.¹² The analysis showed that 2.8% of occult primary cases were familial (ie, a parent and offspring were both diagnosed with occult primary cancer). In addition, CUP was associated with the occurrence of lung, kidney, and colorectal cancers in families, suggesting that these tumor types are often the primary sites of the disease.¹² A latent primary cancer may emerge during the natural course of the disease, although it is uncommon. In 20% to 50% of patients, the primary tumor is not identified even after postmortem examination.^{8,13,14} Some data also suggest an epidemiologic correlation between smoking and risk of developing CUP.¹⁵ A literature review found strong associations between CUP risk and smoking frequency (>20 cigarettes per day) as compared to individuals who never smoked. Individuals who smoked ≥40 years also had an increased likelihood of developing CUP (multivariable adjusted hazard ratio [HR], 1.45; 95%

NCCN Guidelines Version 2.2025

Occult Primary

confidence interval [CI], 1.09–1.94; $P_{\text{trend}} = .02$) when compared to those who never smoked.

Presentation and Prognosis

Multiple sites of involvement are observed in >50% of patients with CUP.¹⁶ Common sites of involvement are the liver, lungs, bones, and lymph nodes.^{16,17} Although certain patterns of metastases suggest possible primary sites, CUP can metastasize to any site. Therefore, physicians should not rely on patterns of known metastases to determine the primary site in patients with CUP.

About 80% of patients with CUP have a poor prognosis and median OS of 3 to 10 months.^{2,18} In general, adenocarcinomas and undifferentiated tumors have a worse prognosis than SCC (3.5% vs. 41.6% 3-year survival).² Other unfavorable prognostic features include male gender assigned at birth; older age (≥ 65 years); poor performance status (PS); multiple comorbidities; metastases involving multiple organs (eg, liver, lung, bone); nonpapillary malignant ascites (adenocarcinoma); peritoneal metastases; multiple cerebral metastases; and adenocarcinoma with multiple lung/pleural or bone lesions.^{2,19-21} For these patients, an empiric approach to therapy is recommended, although the likelihood of survival benefit is questionable.

The 20% of patients with CUP with a more favorable prognosis include those with a single, small, and potentially resectable tumor; poorly differentiated carcinoma with midline nodal distribution; SCC involving cervical lymph nodes (constituting 2%–5% of all cases of occult primary cancers²²); isolated inguinal adenopathy (SCC); poorly differentiated neuroendocrine (PDNE) carcinomas; women with papillary adenocarcinoma of the peritoneal cavity; women with adenocarcinoma involving only axillary lymph nodes; and men with blastic bone metastases and elevated prostate-specific antigen (PSA; adenocarcinoma).^{2,19,23,24} For patients with favorable prognostic features, tailored approaches to

treatment, such as locoregional treatments or specific systemic therapy regimens (eg, fluorouracil-based therapy for suspected colon primary or cisplatin-based therapy for possible germ cell tumor), are likely to provide clinical benefit and may prolong survival.

A robust prognostic model and nomogram to predict OS in patients with CUP was recently developed and externally validated using a large multicenter cohort of 926 patients.⁵ Five independent prognostic factors were identified: gender assigned at birth, Eastern Cooperative Oncology Group (ECOG) PS, histology, number of metastatic sites, and neutrophil-lymphocyte ratio. Male gender assigned at birth, poor ECOG PS, adenocarcinoma histology, high number of metastatic sites, and high neutrophil-lymphocyte ratio were associated with worse survival in the Cox regression model. ECOG PS and neutrophil-lymphocyte ratio were the strongest predictors of OS ($P < .001$). The resulting model predicted OS with superior performance (concordance probability estimate [CPE] of 0.69 and concordance index of 0.71) compared with traditional prognostic classifiers. This model uses universally available baseline factors to ensure feasibility of use in diverse settings and can potentially aid in clinical decision-making as well as clinical trial selection and stratification.

Pathology

CUP can be classified into five major subtypes after routine evaluation with light microscopy. The most frequently occurring subtype is well- or moderately differentiated adenocarcinoma (60%), followed by poorly differentiated adenocarcinoma (25%), SCC (5%), undifferentiated carcinoma (5%), and neuroendocrine tumors (5%).^{1,2} CUP often has multiple chromosomal abnormalities and overexpression of several genes, including *EGFR*, *MET*, *JAK3*, *BRAF*, *PIK3CA*, *c-kit/PDGFR* (*PDGFRα* or *PDGFRβ*), *RAS*, *BCL2*, *HER2*, and *TP53*.^{9,25-27} The *BRD4-NUT* oncogene, resulting from the chromosomal translocation t(15;19), has been identified in children and young adults with carcinoma of midline structures and

NCCN Guidelines Version 2.2025

Occult Primary

unclear primary sites.^{1,29,30} Other chromosomal abnormalities frequently observed in CUP are activation of angiogenesis genes (50%–89% of CUP tumors), oncogene overexpression (10%–30%), epithelial-to-mesenchymal transition marker elevation (16%), and activation of hypoxia-related proteins (25%) and intracellular signaling molecules (20%–35%).² A study that performed targeted gene panel sequencing in a series of 252 patients with CUP found that the most common genetic alterations were deletions in the tumor suppressor genes *p53* (49.6%), *CDKN2A* (19.0%), and *NOTCH1* (14.1%) as well as activation of the oncogenes *KRAS* (23.4%), *FGFR4* (14.9%), and *PIK3CA* (10.7%).³¹ Both *KRAS* activation and *CDKN2A* deletion were associated with poor prognosis. Additionally, chromosomal instability has been suggested as a possible cause or prognostic factor for more aggressive presentations of CUP.^{2,32}

In an attempt to identify the tissue of origin, biopsy specimens are often analyzed by immunohistochemistry (IHC).^{33–36} Gene expression profiling (GEP) assays have also been developed to attempt to identify the tissue of origin in patients with occult primary cancers.^{37–39} Both methodologies offer a similar range of accuracy in tumor classification (approximately 75%).⁴⁰ While there may be a diagnostic benefit to GEP, a clinical benefit has not been demonstrated. Consequently, the Panel does not currently recommend use of gene sequencing to predict tissue of origin. Until more robust outcomes and comparative effectiveness data are available, pathologists and oncologists must collaborate on the judicious use of IHC and GEP on a case-by-case basis, with the best possible individualized patient outcome in mind.⁴¹

Immunohistochemistry

IHC studies are useful for the characterization of CUP tumors by providing information about tumor lineage, cell type, and pathologic diagnosis.^{33–36,42} The use of IHC in CUP is based on the premise that concordance exists in the expression profiles of primary and metastatic cancers.^{37,39} The

predictive value of IHC panels improves with the recognition of patterns that are strongly indicative of specific tumors. However, limitations of IHC testing include factors affecting tissue antigenicity, interobserver and intraobserver variability in interpretation, tissue heterogeneity, and inadequate biopsy samples. Nevertheless, with well-performed and interpreted IHC panels, pathologists can identify the putative site of origin of CUP in about 75% of samples (however, validation to determine accuracy is a challenge given the unknown primary cancer designation).⁴⁰ Exhaustive IHC studies (in excess of 10–12 stains) have not been shown to increase the diagnostic accuracy in identifying the putative primary sites.⁴³ Therefore, testing a large series of IHC markers in individual patients should be avoided.

To determine tissue of origin using IHC, a tiered approach is recommended to conserve the diagnostic material. A first tier of IHC assays can be used to help determine tissue lineage using lineage-restricted markers (eg, carcinoma, sarcoma, lymphoma, melanoma). A second tier of IHC, using organ-specific markers, can be used to help suggest the putative primary site.⁴⁰ In select patients, it may be helpful to use a third tier of testing for tumor biomarkers that might inform treatment decisions, such as *RAS*, *HER2*, or *ALK* rearrangements. Per physician discretion, TRK protein testing can be considered as part of broad IHC testing (a positive test should be confirmed with next-generation sequencing [NGS]).^{44,45} IHC studies should be used in conjunction with imaging studies to select the best possible treatment options for patients with CUP.

In Situ Hybridization

The use of in situ hybridization (ISH) studies in CUP tumors is critical for evaluating chromosomal aberrations including translocations, insertions or inversions, deletions, and amplifications.⁴⁶ The utility of ISH in CUP is multifaceted and can provide information that may aid in the identification of the primary tumor or in guiding treatment. Detected genetic changes

NCCN Guidelines Version 2.2025

Occult Primary

(ie, HER2 positivity) can help predict sensitivity to certain targeted agents.⁴⁷ Select chromosomal errors may help delineate solid tumors, potentially leading to identification of the primary site. In a study of 85 patients with metastatic head and neck SCC, human papillomavirus (HPV) (p16) analysis via ISH was conducted as part of the clinical workup.⁴⁸ Of the 60 p16-positive samples, 98% correlated with the presence of HPV via ISH. In cancers of the head and neck, p16 positivity is prognosticative of oropharyngeal origin ($P < .001$). Limitations to ISH include factors relating to the complexity of ISH testing, that of which is more cumbersome than IHC testing.⁴⁹ Historically, ISH also has decreased sensitivity to low-expression genes or short transcripts. The emergence of new and informative IHC markers, and recent advances in testing methodologies and test sensitivity in ISH, will likely continue to aid in the diagnosis of CUP.^{49,50} See *Immunohistochemistry/In Situ Hybridization Markers for Unknown Primary Cancers* in the algorithm for suggested IHC markers.

Molecular Profiling

Recent advances in molecular profiling techniques can potentially offer new therapy options to patients with CUP; however, the clinical benefit of using molecular profiling to guide treatment decisions in CUP remains to be determined. There are two main applications for molecular profiling in the management of CUP. The first application utilizes GEP and molecular cancer classifier assays to determine the tissue of origin to guide site-specific therapy. The second application utilizes NGS to identify genomic aberrations that can be targeted therapeutically.

GEP and Molecular Cancer Classifier Assays for Tissue of Origin

Over the past decade, several studies have examined various molecular assays designed to identify the tissue of origin in CUP.^{39,51} These assays are designed based on the assumption that metastatic tumors will have a

similar molecular profile to that of the primary tumor. Assays used in GEP utilize messenger RNA (mRNA)-, DNA-, or microRNA (miRNA)-based platforms, which analyze anywhere between 10 and 2000 genes simultaneously and can distinguish between 6 and 50 different cancer types.⁵²⁻⁶¹ When compared to samples from known tumor types, these assays have generally demonstrated an accuracy rate of 83% to 94% in determining the tissue of origin.⁶² However, because it is difficult to confirm the site of origin in most cases of CUP, the accuracy of GEP assays in occult primary tumor samples is challenging to determine. Surrogate measures used to determine accuracy include correlation with IHC findings, clinical presentation/response to therapy, as well as the appearance of latent disease at the primary tumor site.^{39,51} Several studies suggest that the accuracy of GEP profiling is comparable or superior to the accuracy of IHC for poorly differentiated/undifferentiated carcinomas.^{43,62,63}

Several commercially available GEP tests have been evaluated in prospective clinical studies in an attempt to determine if the information they provide regarding tissue of origin translates into clinically meaningful benefits for patients.⁶⁴ Comparisons between commercially available GEP tests have also been published.^{39,41,51} Currently, there is no evidence of improved outcomes with the use of site-specific therapy guided by molecular testing results in patients with CUP. Results from a prospective phase II study of 194 patients with CUP in which treatments were based on the identification of primary sites by a 92-gene assay showed that clinical features and response to treatment were generally consistent with assay results.⁶⁴ However, while the median survival time of 12.5 months in the subset of patients who received GEP-directed treatment was better than the predefined historical cohort, the difference was small and similar results could be expected from empiric use of these regimens in a good PS group of patients with CUP predominantly below the diaphragm. In a randomized phase II trial conducted in Japan, GEP-based site-specific

NCCN Guidelines Version 2.2025

Occult Primary

treatment did not significantly improve 1-year survival rates compared with empirical carboplatin plus paclitaxel in patients with CUP.⁶⁵ The randomized phase III GEFCAP104 trial directly compared the clinical effectiveness of systemic treatment based on GEP results to empirical chemotherapy with cisplatin and gemcitabine in 243 European patients with CUP.⁶⁶ Median progression-free survival (PFS) and OS were similar between the two groups. Although GEP-based site-specific treatment did not improve outcomes, it is important to note that many patients in this trial had cancers that are difficult to treat and for which no targeted therapies are available (ie, pancreatico-biliary cancer). Molecular testing in a small number of patients with suspected primary cancers unlikely to respond to empirical chemotherapy allowed the use of a targeted agent or better tailored therapy. However, there were not enough of these patients to impact the overall trial results. Thus, the clinical benefit that might be derived from the use of GEP assays, if any, remains to be determined.

Mutational Testing with Next-Generation Sequencing

Since the identification of clinically relevant genomic alterations has the potential to influence therapy options, use of standardized comprehensive NGS assays may help identify novel treatment paradigms to address the limited treatment options and poor prognoses of patients with CUP.⁶⁷⁻⁷⁰ The ability of NGS to identify potentially actionable mutations in patients with CUP varies widely in the literature. Depending on the study, mutations with potential therapeutic relevance have been identified in 30% to 85% of patients with CUP.^{21,67,71-75} The wide reported variation in the detection of actionable mutations by NGS in patients with CUP may be attributed to the different NGS assays, gene panels, analysis tools, and definitions for what is considered an actionable mutation used across the different studies. In a study by Ross et al, use of a hybrid-capture–based NGS assay enabled the identification of at least one potentially actionable genomic alteration in 85% of the 200 CUP specimens analyzed.⁶⁷ However, only 13% of patients had alterations associated with U.S. Food

and Drug Administration (FDA)-approved targeted therapies.²¹ In an updated analysis by the same group, 32% of the 303 patients with CUP analyzed had actionable genomic alterations associated with FDA-approved targeted therapies, including alterations in programmed death ligand 1 (PD-L1) expression, microsatellite instability (MSI) status, and tumor mutational burden (TMB).⁷⁵ Similarly, a study by Varghese et al, which defined an actionable mutation as a specific molecular alteration that is linked to a drug response by an FDA approval or other high-level clinical evidence, found actionable genomic alterations in 30% of patients with CUP.⁷⁴ Another study analyzed the mutation and copy number profile of 1709 CUP samples in the GENIE cohort to identify potential targeted treatment options.⁷⁶ Fifty two significantly mutated genes were detected, in which 13 (25%) had approved (or undergoing clinical trials) targeted therapy options available. In a large study by Kato et al, comprehensive genomic profiling identified genomic alterations potentially targetable by FDA-approved agents in 63.8% of the 442 patients with CUP who were tested.⁷³ Using multi-platform profiling, including IHC, gene sequencing, and ISH, Gatalica et al identified actionable mutations in 96% of 1806 CUP cases.⁷² However, most of these were identified using established IHC techniques. Importantly, 4 years after the publication of this study, the authors used a 592-gene panel to profile 389 CUP cases and found that only 28% were associated with therapeutically targetable mutations.⁷⁷

To date, there is a lack of high-level evidence to suggest that use of targeted therapies based on NGS results improves outcomes in patients with CUP. The phase II, randomized, international CUPISCO trial assessed the clinical benefit of NGS-directed targeted therapy in 528 participants by directly comparing the efficacy of empirical platinum-based chemotherapy with molecularly targeted therapies relevant to the aberrations found by genomic profiling in patients with histologically confirmed CUP. The primary endpoint was PFS; secondary endpoints included OS, overall response rate (ORR), duration of response, and

NCCN Guidelines Version 2.2025

Occult Primary

percentage of patients with adverse events. This trial has recently closed and results are pending (Clinical Trial ID: [NCT03498521](#)).

Initial Evaluation

Patients with a suspected metastatic malignancy should undergo a complete history and physical examination (including breast, genitourinary, pelvic, rectal, skin, and/or oral cavity examinations as appropriate) with a detailed review of past biopsies or malignancies, removed lesions, spontaneously regressing lesions, and existing imaging studies. Routine laboratory tests (ie, complete blood count [CBC], electrolytes, liver function tests, creatinine, calcium) and contrast-enhanced chest/abdomen/pelvis CT scans with IV contrast are also recommended. Clinically directed endoscopy, urinalysis [UA], hemocult test, and measurement of lactate dehydrogenase (LDH) can be included in the initial evaluation, if indicated.

Diagnostic Imaging

Imaging can play an integral role in the multidisciplinary diagnostic evaluation of patients with CUP.⁷⁸ CT is the most frequently used imaging modality in the management of occult primary cancers. PET scan has been shown to be useful for the diagnosis, staging, and restaging of many malignancies,^{79,80} and might be warranted in some situations for CUP. PET scan has shown intermediate specificity and high sensitivity in a few small studies, but larger randomized studies are required to determine the clinical utility of PET in patients with CUP.^{4,78,81} In a comprehensive review of 10 published studies, Seve et al concluded that PET is a valuable imaging modality for patients with CUP with a single site of metastasis if therapy with a curative intent is planned.⁸² Cumulative data from a meta-analysis examining PET as a diagnostic tool in 246 patients with cervical nodal metastases of unknown primary tumors demonstrated a tumor detection rate of 44% and a sensitivity and specificity rate of 97% and 68%, respectively.⁸³

One of the limitations of PET has been the limited accuracy of anatomic localization of functional abnormalities because of very little accumulation of 18F-fluorodeoxyglucose (FDG) tracer in some neoplastic tissues. In these cases, the combination of PET with either CT or MRI can provide more useful information.^{84,85} Several studies have reported that the combination of PET/CT identified the primary site in 25% to 75% of patients with CUP.⁸⁶⁻⁹⁴ A multicentric diagnostic accuracy test study assessed the role of FDG-PET/CT in the detection of primary tumors in 175 patients with CUP.⁹⁵ Lesions indicative of malignant primary tumors were detected in 60% of patients and pathologically proven in 57.1%. Results also showed a sensitivity of 100% and specificity of 93.3%. In a prospective study of 56 patients with CUP, the sensitivity and accuracy of PET/CT for the detection of primary tumors were significantly higher than the sensitivity and accuracy of CT/MRI (69% and 77% vs. 41% and 48%, respectively; $P < .04$).⁹⁶ PET/CT has also been shown to improve the accuracy of staging CUP by detecting more metastases than CT alone.⁹⁷ Although one study suggested that PET/CT detected more primary sites (24%–40%) than conventional CT (20%–27%),⁹⁸ the exact role of PET/CT remains undefined because of the lack of large prospective clinical trials comparing PET/CT with conventional imaging modalities. Therefore, the Panel recommends using FDG-PET/CT as an alternative to CT/MRI for the initial evaluation only in patients with a contraindication to contrast enhancement. However, FDG-PET/CT may be warranted in some other situations, especially when considering local or regional therapy.

Combined modality screening with PET/MRI has been evaluated in several studies for its diagnostic significance in CUP. In a preliminary comparison trial to evaluate the diagnostic potential of whole-body PET/MRI versus PET/CT, Ruhlmann et al found that both hybrid imaging techniques provide a comparable diagnostic ability for detection of the primary cancer site in patients with CUP.⁹⁹ Furthermore, due to the significantly lower dose of ionizing radiation (IR), PET/MRI may serve as

NCCN Guidelines Version 2.2025

Occult Primary

an alternative to PET/CT, particularly for therapy monitoring and long-term surveillance.⁹⁹ In a prospective study by Sekine et al, 43 patients with suspected CUP were assessed with PET/CT and PET/MRI for the presence of a primary tumor, lymph node metastases, and distant metastases.¹⁰⁰ PET/MRI was found to be superior to PET/CT for primary tumor detection (sensitivity/specificity, 85%/97% vs. 69%/73%; $P = .02$) and comparable to PET/CT for the detection of lymph node metastases (93%/100% vs. 93%/93%; $P = .157$) and distant metastases (100%/97% vs. 82%/100%; $P = .564$). PET/CT also tended to misclassify physiologic uptake of FDG as malignancy compared with PET/MRI.¹⁰⁰

Advances in MRI technology have enabled the emergence of more sensitive and accurate techniques. Multiparametric MRI (MPMRI), which consists of three separate imaging parameters (T2-weighted imaging, diffusion-weighted imaging, and dynamic contrast-enhanced imaging), allows for detailed visualization of tissues as well as their chemical makeup, enabling experienced radiologists to better separate cancerous tissue from benign tissue. In a retrospective study of 38 patients with CUP and cervical lymph node metastases, the accuracy of PET/CT and MPMRI in locating the primary tumor in the neck region was identical, with MPMRI having the added advantage of sparing patients the exposure to IR.¹⁰¹ T1-weighted high-resolution isotropic volume examination (THRIVE) is a 3D ultrafast spoiled gradient MRI sequence that provides more detailed anatomic information and improved spatial resolution with reduced artifacts when compared to traditional 2D spin-echo MRI. In a retrospective study of 73 patients with CUP and cervical lymph node metastases, 3D-THRIVE MRI enabled the identification of the primary tumor in 72.9% of patients compared to 49.2% and 36.4%, respectively, for spin-echo MRI and contrast-enhanced CT.¹⁰² The diagnostic accuracy of 3D-THRIVE MRI (71.2%) was found to be higher than the accuracies of spin-echo MRI (53.4%) and CT (46.4%; $P = .001$). Therefore, because of their lower IR dose levels and either identical or improved efficacy and

accuracy, PET/MRI, MPMRI, and 3D-THRIVE MRI may be favorable over PET/CT scans in the workup of suspected occult malignancies. However, more robust data from randomized prospective trials that include treatment outcome and patient survival data are required to support this assertion.

Workup

Patients with a suspected occult primary tumor should undergo an initial core needle biopsy (preferred) and/or fine-needle aspiration (FNA) with cell block of the most accessible site. Accurate pathologic assessment of the biopsied material is of utmost importance. Therefore, a pathologist must be consulted to determine the adequacy of the specimen and to perform additional studies including IHC stains or ISH testing. If available, the pathologist should provide rapid on-site evaluation (ROSE) and confirm adequate sampling of the lesion.^{103,104} If additional biopsy material is necessary, a core needle, incisional, or excisional biopsy may be performed. Examination of the biopsy material by light microscopy is usually performed first. Other techniques include electron microscopy and flow cytometry. Although IHC stains can be informative (see *Immunohistochemistry* above), large panels of IHC markers should be avoided.

MSI/mismatch repair (MMR) testing is indicated for patients with CUP; however, it should be noted that the population of patients with MSI-high/MMR-deficient (MSI-H/dMMR) occult primary tumors is generally low. In a comprehensive analysis of 389 CUP tumors, only 1.8% of tumors were MSI-H.⁷⁷ Determination of TMB by a validated and/or FDA-approved assay is a category 2B recommendation.¹⁰⁵ Molecular profiling of tumor tissue using NGS or other technique to identify gene fusions can be considered after an initial determination of histology has been made. Tumor/somatic molecular profiling should be considered for patients who are candidates for anti-cancer therapy to identify uncommon mutations (ie, *RET* fusions). Testing on tumor tissue is preferred; however, cell-free

NCCN Guidelines Version 2.2025

Occult Primary

DNA testing can be considered if tumor tissue testing is not feasible. The Panel does not recommend tissue-of-origin studies.

At this point, a specific pathologic diagnosis may be made (ie, epithelial occult primary [not site-specific], lymphoma or other hematologic malignancy, thyroid carcinoma, melanoma, sarcoma, germ cell tumor). Other diagnostic studies should be based on clinical presentation and subsequent histopathologic findings. This initial evaluation will identify a primary site in approximately 30% of patients presenting with CUP. These patients should be treated according to the appropriate NCCN Guidelines for Treatment by Cancer Type (see list of [NCCN Guidelines for Treatment by Cancer Type](#)). For the remaining patients, a great deal of controversy exists regarding whether an exhaustive, time-consuming, and costly evaluation should be conducted to search for the primary tumor beyond these initial tests, as opposed to a more directed evaluation based on the complete history and physical examination, clinical presentation, histopathologic diagnosis, and metastatic sites of involvement. Suggested diagnostic tests for each pathologic subtype, location, and anatomic site (where applicable) are indicated in the algorithm and are discussed below. Additional studies can be important in determining whether the occult primary cancer is potentially curable, or in diagnosing a possibly treatable disease associated with long-term survival.

Workup for Possible Breast Primary

Adenocarcinoma with positive axillary and/or mediastinal nodes in individuals with intact breast tissue (including gynecomastia) is highly suggestive of a breast primary site. Adenocarcinoma in the supraclavicular nodes, chest, peritoneum, retroperitoneum, liver, bone, or brain could also indicate primary breast cancer. Therefore, mammogram is indicated for these patients. For patients with a non-diagnostic mammogram and histopathologic evidence of breast cancer, contrast-enhanced MRI and/or ultrasound of the breast should be considered. Contrast-enhanced breast

MRI (if not contraindicated) should also be considered when mammography is not adequate to assess the extent of the disease, especially in individuals with dense breast tissue and/or positive axillary nodes, or to evaluate the chest wall.¹⁰⁶ Breast MRI has been shown to be useful in identifying the primary site in patients with occult primary breast cancer and may also facilitate breast conservation in select patients by allowing for lumpectomy instead of mastectomy.^{107,108} In one report, MRI identified the breast as the primary site in approximately half of the patients presenting with axillary metastases, irrespective of breast density.¹⁰⁹

For patients with involvement of the mediastinum whose workup does not indicate primary breast cancer, additional consultation with a pathologist to determine whether further analysis would help differentiate between breast and non-small cell lung cancer (or other putative primary sites) should be considered.

Workup for Possible Testicular Germ Cell Primary

Adenocarcinoma with positive mediastinal nodes in patients with testes who are <50 years suggests a possible primary testicular germ cell tumor, as does a retroperitoneal mass in such patients <65 years of age.

Measurement of the serum tumor markers β -human chorionic gonadotropin (β -hCG) and α -fetoprotein (AFP) is recommended; testicular ultrasound is indicated for patients found to have elevated levels of serum β -hCG or AFP. For patients who have involvement of the mediastinum and whose workup does not indicate a primary germ cell tumor, additional consultation with a pathologist to determine whether further analysis would help differentiate between testicular and non-small cell lung cancer should be considered.

NCCN Guidelines Version 2.2025

Occult Primary

Workup for Possible Ovarian Primary

Adenocarcinoma with positive mediastinal nodes in patients with ovaries present who are <50 years is suggestive of an ovarian primary tumor. Adenocarcinoma in the inguinal nodes, chest (multiple nodules), or peritoneum (with or without ascites) also suggests possible primary ovarian cancer, as does the presence of pleural effusion or a retroperitoneal mass. Testing for the ovarian cancer marker CA-125 is recommended in these cases, as is consultation with a gynecologic oncologist. For patients who have involvement of the mediastinum but whose workup does not indicate a primary ovarian tumor, consider treating for germ cell tumors (including poor-risk germ cell tumors) or non-small cell lung cancer based on the age of the individual.

Workup for Possible Prostate Primary

All patients with a prostate (or post-prostatectomy) who are >40 years with an adenocarcinoma of unknown primary, except for those with metastases limited to the liver or brain, should undergo testing for PSA levels. In addition, patients presenting with bone metastases or multiple sites of involvement should have PSA levels assessed regardless of age.

Additional Workup for Localized Adenocarcinoma or Carcinoma Not Otherwise Specified

In patients with adenocarcinoma involving painful bone lesions, a contrast-enhanced chest/abdomen/pelvis CT with bone scan is indicated. For patients presenting with a retroperitoneal mass, peritoneal mass, or ascites, urine cytology is recommended followed by cystoscopy if findings are suspicious. In patients with inguinal lymph node involvement, the guidelines include proctoscopy, if clinically indicated, to assess for rectal or anal cancer.¹¹⁰ Endoscopic evaluation is recommended for patients presenting with malignancy in the liver and is suggested for patients with positive supraclavicular nodes, if clinically indicated. However, endoscopy

is not routinely recommended for patients presenting with malignant ascites (ie, peritoneal presentation). Since the differentiation between metastatic adenocarcinoma of the liver and primary hepatocellular carcinoma (HCC) is sometimes challenging, the use of AFP as a marker for HCC is recommended as part of the additional workup for CUP in the liver.¹¹¹ In the absence of a positive fecal occult blood test or other clinical factors suggesting a putative colon primary or concern for bowel involvement/obstruction from metastatic cancer or carcinomatosis, the diagnostic yield of colonoscopy is low and is therefore not recommended as standard practice in the workup process of CUP.¹¹²

Workup for Squamous Cell Carcinoma

SCC can be present in the lymph nodes of the head and neck region, as well as in the supraclavicular, axillary, and inguinal nodes. Contrast-enhanced CT scans of the abdomen and pelvis, careful perineal and lower extremity examination including reproductive organs and genitalia, gynecologic oncology consult, and anal endoscopy are recommended for patients with SCC involving inguinal lymph nodes. PET/CT can be considered as an alternative for patients with a contraindication to contrast enhancement. Cystoscopy can also be considered, if clinically indicated. Chest CT is recommended for patients with SCC involving the axillary nodes. The workup recommendations for Occult Primary in the [NCCN Guidelines for Head and Neck Cancers](#) should be followed for patients with unknown primary lesions in the head and neck region or supraclavicular nodes. Importantly, clinicians should check results of p16 IHC, HPV ISH, and Epstein-Barr virus (EBV) ISH since positive results may help localize the primary site.

A bone scan (if only chest/abdomen/pelvis CT scan was previously done) and diagnostic imaging studies are recommended for SCC involving painful bone lesions. Directives for diagnostic imaging in this context have

NCCN Guidelines Version 2.2025

Occult Primary

been previously described under *Additional Workup for Localized Adenocarcinoma or Carcinoma Not Otherwise Specified* above.

Workup for Neuroendocrine Tumors

Neuroendocrine tumors can metastasize to several sites, including the head and neck, supraclavicular lymph nodes, lung, inguinal lymph nodes, liver, bone, brain, and skin. The workup recommendations for *Neuroendocrine Tumors of Unknown Primary* in the [NCCN Guidelines for Neuroendocrine and Adrenal Tumors](#) should be followed for patients with suspected primary neuroendocrine tumors.

Management

Psychosocial Distress

For many patients, the apparent uncertainties surrounding the diagnosis of an unknown primary cancer may result in significant psychosocial distress and increased difficulty in accepting treatment options. A study by Hyphantis et al found that psychiatric manifestations, including anxiety and depression, were more common in patients with CUP than in those with known primary cancers.¹¹³ Empathetic discussion about the natural history of these types of cancers, their prognoses, and the provision of support and counseling by both the primary oncology team and specialized services may help alleviate this distress. Please see the [NCCN Guidelines for Distress Management](#) for further information.

Supportive Care

In addition to psychosocial support, patients with active and incurable CUP often require symptom management and palliative care interventions. Given the natural history of this disease, end-of-life discussions should be initiated early in the clinical course. Hospice care should also be considered and utilized as appropriate. Please see the [NCCN Guidelines](#)

[for Palliative Care](#) and the [NCCN Guidelines for Survivorship](#) for more information.

Treatment Based on Workup Findings

Adenocarcinoma

Localized adenocarcinoma or carcinoma not otherwise specified is treated according to the most likely primary site. Patients with localized adenocarcinoma or carcinoma not otherwise specified involving supraclavicular nodes or the head and neck regions should be treated according to the Occult Primary pathway described in the [NCCN Guidelines for Head and Neck Cancers](#). Patients with localized adenocarcinoma involving axillary nodes as well as those who are breast-marker positive and have pleural effusion should be treated according to the [NCCN Guidelines for Breast Cancer](#). Patients with localized adenocarcinoma with a peritoneal mass or ascites consistent with ovarian histology should be treated according to the [NCCN Guidelines for Ovarian Cancer](#). Patients with a retroperitoneal mass consistent with germ cell histology should be treated according to the [NCCN Guidelines for Testicular Cancer](#) or [NCCN Guidelines for Ovarian Cancer](#), respectively.

Localized adenocarcinoma occurring in the mediastinum most likely derives from either a germ cell tumor or a non-small cell lung tumor. Patients <40 years and those between 40 and 50 years should be treated for poor-risk germ cell tumors according to the [NCCN Guidelines for Testicular Cancer](#) or the [NCCN Guidelines for Ovarian Cancer](#). Alternatively, patients aged 40 to 50 years could also be treated according to the [NCCN Guidelines for Non-Small Cell Lung Cancer](#). Patients aged ≥50 years should be treated according to the [NCCN Guidelines for Non-Small Cell Lung Cancer](#).

Other locations of adenocarcinomas of unknown primary are not associated with a common primary site. Treatment recommendations in

NCCN Guidelines Version 2.2025

Occult Primary

these cases are thus general and may involve local and/or systemic therapies. For example, axillary node dissection is recommended for patients with a prostate (or post-prostatectomy) with localized adenocarcinoma involving the axillary nodes. Additionally, radiation therapy (RT) or systemic therapy can also be considered if clinically indicated. Patients with completely resectable lung nodules should be considered for surgery. Systemic therapy, preferably as part of a clinical trial, or stereotactic body RT (SBRT) can be considered for oligometastatic lung nodules with or without resection. Lymph node dissection is recommended for inguinal nodal involvement; RT with or without systemic therapy can also be considered if clinically indicated. It should be noted that the use of RT alone in cases of bilateral inguinal node involvement is a category 2B recommendation.¹¹⁴

Surgical resection with or without systemic therapy is recommended for patients with localized adenocarcinoma in the liver. If surgery is medically contraindicated or declined by the patient, or if the tumor is unresectable, recommended systemic therapy and/or locoregional treatment options as described in the [NCCN Guidelines for Hepatocellular Carcinoma](#) should be followed.

For patients with good PS and bone lesions with potential for fracture in weight-bearing areas, surgery and RT are recommended. In the case of patients with poor PS, RT without surgery is recommended. Patients with brain metastases should be treated according to the recommendations for treating metastatic lesions in the [NCCN Guidelines for Central Nervous System Cancers](#). Systemic therapy (preferably within a clinical trial) can be considered for patients presenting with breast marker-negative pleural effusion or ascites/peritoneal mass of non-ovarian origin. In the case of a retroperitoneal mass of non-germ cell histology, surgery and/or RT is recommended, with systemic therapy considered only for select patients.

Efforts should be made to control symptoms in patients with disseminated adenocarcinoma of unknown primary. The preferred treatment approach

for these patients is enrollment in a clinical trial. Additional recommendations include consideration of systemic therapy on an individual basis and specialized approaches (see *Specialized Approaches* below).

SCC

In patients with site-specific SCC and localized axillary or inguinal lymph node involvement, lymph node dissection is recommended. RT with or without systemic therapy can be considered if clinically indicated (the use of RT alone in the case of bilateral inguinal node involvement is a category 2B recommendation).¹¹⁴ Systemic therapy is not recommended if the tumor has a high likelihood of cutaneous origin.

Patients with involvement of SCC in the supraclavicular lymph nodes or in the head and neck regions should be treated according to the recommendations for occult primary tumors described in the [NCCN Guidelines for Head and Neck Cancers](#). Patients with site-specific SCC in the mediastinum should be treated according to the [NCCN Guidelines for Non-Small Cell Lung Cancer](#). Participation in a clinical trial is the preferred treatment option for patients with multiple lung nodules or pleural effusion. Systemic therapy can also be considered.

Surgery and RT are recommended for patients with good PS and bone lesions with potential for fracture in weight-bearing areas. For patients with poor PS, RT alone is recommended. Patients with brain metastases should be treated according to the recommendations for metastatic lesions in the [NCCN Guidelines for Central Nervous System Cancers](#).

Efforts should be made to control symptoms in patients with disseminated SCC of unknown primary. Enrollment in a clinical trial is the preferred treatment option for these patients. Systemic therapy can be considered on an individual basis.

NCCN Guidelines Version 2.2025

Occult Primary

Neuroendocrine Tumors

Treatment of suspected neuroendocrine tumors should follow the Neuroendocrine Unknown Primary pathway of the [NCCN Guidelines for Neuroendocrine and Adrenal Tumors](#).

Systemic Therapy

Many systemic therapy regimens have been evaluated in patients with CUP in an attempt to prolong survival and provide symptom relief. Various regimens have shown efficacy in the treatment of patients with CUP in phase II studies. However, a 2012 systematic review of chemotherapy trials in patients with CUP of unfavorable presentations concluded that no specific regimen can be recommended as standard of care.¹¹⁵ Historically, response rates of around 20% and median OS of 6 months have been observed in patients with CUP treated with taxane- or platinum-based regimens.^{116,117} A systematic review and meta-analysis published in 2013 largely reached the same conclusion, with taxanes showing a possible slight advantage over platinum-based regimens.¹¹⁸ In general, systemic therapy shows limited efficacy and considerable toxicity in patients with CUP. Therefore, these guidelines recommend that systemic therapy for patients with disseminated disease be limited to patients who are symptomatic with a PS of 1–2 or to patients who are asymptomatic with aggressive cancer and a PS of 0. The choice of regimen should be based on the histologic type of cancer. Regimens in addition to those listed in the guidelines can be considered.

Adenocarcinoma

Poorly differentiated or undifferentiated occult primary tumors respond differently from well- to moderately differentiated occult primary tumors. Tumors in the former group seem to be highly responsive to cisplatin-based combination chemotherapy.^{119,120} ORRs reported in two studies from the early 1990s were 53% (van der Gaast et al¹²⁰) and 63%

(Hainsworth et al¹¹⁹) with complete response rates of 12% and 26%, respectively, with cisplatin-based regimens. In one study, patients who had tumors with extragonadal germ cell features showed an especially high response rate.¹¹⁹ In the other, patients with undifferentiated carcinomas had a better response rate than those with poorly differentiated carcinomas (79% vs. 35%; $P = .02$).¹²⁰ Taxane-based chemotherapy has also been associated with long-term survival in some patients with CUP, with 1-, 2-, 3-, and 4-year survival rates of 42%, 22%, 17%, and 17%, respectively, and a median survival of 10 months.¹²¹

The following regimens are included in the algorithm for treating adenocarcinoma of unknown primary based on the results of phase II and/or phase III studies, as described below. Regimens other than those listed can also be considered. It is important to note that leucovorin is indicated with certain fluorouracil-based regimens. However, depending on availability, these regimens may be used with or without leucovorin. For more information regarding the leucovorin shortage, see below.

Paclitaxel and Carboplatin with or without Etoposide

The combination of paclitaxel and carboplatin is commonly used to treat non-small cell lung and esophageal cancers.¹²²⁻¹²⁸ The combination of paclitaxel and carboplatin (with or without etoposide) was found to be effective for the treatment of adenocarcinoma of unknown primary in several studies.^{121,129-133} In the phase II Hellenic Cooperative Oncology Group study, the combination of paclitaxel and carboplatin was well tolerated and produced an ORR of 38.7%.¹²⁹ In a randomized prospective phase II study conducted by the German CUP Study Group, paclitaxel and carboplatin showed better clinical activity than gemcitabine and vinorelbine.¹³³ The median OS, 1-year survival rate, and response rate were 11.0 months, 38%, and 23.8%, respectively, for patients treated with paclitaxel and carboplatin, compared with 7.0 months, 29%, and 20%, respectively, for those treated with gemcitabine and vinorelbine. A phase

NCCN Guidelines Version 2.2025

Occult Primary

III randomized trial found paclitaxel, carboplatin, and etoposide to be an effective regimen in the first-line treatment of patients with CUP.¹³² The ORR was 18% among 93 patients; median PFS and OS were 3.3 months and 7.4 months, respectively; and the 2-year survival rate was 15%. In a phase II trial with long-term follow-up, patients treated with paclitaxel, carboplatin, and etoposide had 2- and 3-year survival rates of 20% and 14%, respectively.¹³⁰ However, overall toxicity is higher with the addition of etoposide than that typically observed with paclitaxel and carboplatin. Therefore, paclitaxel and carboplatin is a preferred regimen for the treatment of occult primary adenocarcinoma while the combination of paclitaxel, carboplatin, and etoposide should be reserved for patients with a PS of 0 to 1 on the ECOG scale.

Gemcitabine and Cisplatin or Docetaxel

The combination of gemcitabine and cisplatin is commonly used to treat non-small cell lung cancer and bladder cancer.^{124,125,134-137} The efficacy of combined gemcitabine and cisplatin for the treatment of CUP was evaluated in the randomized phase II GEFCAP1 01 study.¹³⁸ Well-differentiated adenocarcinoma was the most common histology, with one-fourth of patients having a single metastatic site. Objective responses were observed in 55% of patients (n = 21) receiving gemcitabine and cisplatin and the median survival was 8 months. The follow-up GEFCAP1 02 trial randomly assigned 52 patients 1:1 to receive gemcitabine and cisplatin or cisplatin alone.¹³⁹ Median OS and 1-year survival rates were 11 months and 46% for the gemcitabine and cisplatin arm compared to 8 months and 35% for cisplatin alone. Median PFS was 5 months in the gemcitabine and cisplatin arm and 3 months in the cisplatin arm; 1-year PFS rates were 29% and 15%, respectively.

Gemcitabine and docetaxel was also found to be active and well-tolerated as first-line therapy in patients with CUP.¹⁴⁰ Of 35 patients, 1 complete response and 13 partial responses were observed with an ORR of 40%.

The median time to disease progression was 2 months and the median OS was 10 months. Based on these data, the Panel recommends gemcitabine and cisplatin (preferred) and gemcitabine and docetaxel as treatment options for patients with adenocarcinoma of unknown primary.

Capecitabine with Oxaliplatin (CapeOx) and Fluorouracil/Leucovorin with Oxaliplatin (mFOLFOX6)

The combination of capecitabine and oxaliplatin (CapeOx) has been evaluated in phase II studies for first-line¹⁴¹ and second-line¹⁴² treatment of patients with CUP. As an active and well-tolerated regimen, CapeOx is a preferred option in patients with presumed GI primary adenocarcinoma. A phase II trial involving 51 patients with adenocarcinoma of unknown primary, first-line treatment with CapeOx resulted in an ORR of 11.7%, median PFS of 2.5 months, OS of 7.5 months, and a favorable toxicity profile.¹⁴¹ Second-line treatment with CapeOx resulted in an ORR of 19%, median PFS of 3.7 months, and OS of 9.7 months in a phase II trial of 48 patients with CUP, the majority of whom (65%) had adenocarcinoma of unknown primary.¹⁴²

Although fluorouracil/leucovorin and oxaliplatin (FOLFOX) has not been prospectively evaluated in patients with CUP, FOLFOX has been shown to be equivalent to CapeOx in the treatment of colorectal cancer.¹⁴³⁻¹⁴⁷ The Panel therefore recommends FOLFOX (mFOLFOX6 regimen¹⁴⁸) as a preferred treatment option for patients with presumed GI primary adenocarcinoma.

Fluorouracil/Leucovorin and Irinotecan (FOLFIRI)

The combination of fluorouracil, leucovorin, and irinotecan (FOLFIRI) is commonly used in the first- and second-line treatment of gastrointestinal (GI) cancers.¹⁴⁹⁻¹⁵⁴ The landmark phase III French Intergroup trial, which compared first-line treatment with FOLFIRI to epirubicin, cisplatin, and fluorouracil (ECF) in patients with advanced or metastatic gastric

NCCN Guidelines Version 2.2025

Occult Primary

adenocarcinoma, showed that the median time to treatment failure (TTF) was significantly longer with FOLFIRI than with ECF (5.1 vs. 4.2 months; $P = .008$).¹⁵⁰ While median PFS and OS were similar in the two groups, FOLFIRI was associated with a more favorable toxicity profile than ECF (overall rate of grade 3–4 toxicity, 69% vs. 84%; $P < .001$). Second-line therapy with FOLFIRI has also been shown to be active and well-tolerated in patients with metastatic gastric cancer, recurrent or advanced biliary tract cancer, and locally advanced or metastatic pancreatic cancer.^{151,153}

Data for the efficacy of FOLFIRI in the treatment of patients with CUP are limited. A retrospective study identified 32 patients with CUP predicted to have a colorectal site of origin by molecular profiling who were treated with colorectal cancer regimens, including FOLFIRI.¹⁵⁵ Results showed significantly improved ORRs in patients treated with site-specific regimens such as FOLFIRI compared to empirical regimens used to treat CUP (50% vs. 17%; $P = .0257$). Since a colorectal primary site is among the most common primary sites in CUP,^{156,157} the Panel recommends FOLFIRI as a preferred treatment option for first- or second-line therapy in patients with presumed GI CUP.

Docetaxel and Carboplatin or Cisplatin

Greco et al reported that docetaxel in combination with either cisplatin or carboplatin was active in patients with adenocarcinoma and poorly differentiated CUP.¹⁵⁸ Major response to therapy was observed in 26% of patients receiving docetaxel and cisplatin, with a median survival of 8 months and a 1-year survival rate of 42%. In patients receiving docetaxel and carboplatin, the corresponding response rate was 22%, with a median survival of 8 months and a 1-year survival rate of 29%. Docetaxel in combination with carboplatin was better tolerated than docetaxel with cisplatin in this study.¹⁵⁸

In a phase II Hellenic Cooperative Oncology Group study, treatment with docetaxel and carboplatin every 3 weeks was found to be as safe and effective as palliative treatment for patients with adenocarcinoma or poorly differentiated CUP with a PS of 0 to 2.¹⁵⁹ Median time to progression was 5.5 months and OS was 16.2 months. Combination therapy with docetaxel and cisplatin was examined in a cohort of 29 patients with CUP.¹⁶⁰ Approximately half of these patients (51.7%) had well- to moderately differentiated adenocarcinoma; patients with undifferentiated carcinoma (27.6%) and SCC histologies (13.8%) were also included. The ORR was 37.9%, and median PFS and OS were 6 and 16 months, respectively. Therefore, docetaxel in combination with either cisplatin or carboplatin are recommended treatment options for patients with adenocarcinoma of unknown primary.

Irinotecan and Carboplatin or Gemcitabine

The combination of irinotecan and carboplatin was evaluated in a phase II study of 45 chemotherapy-naïve patients with CUP. The regimen was associated with an ORR of 41.9%; median PFS was 4.8 months and OS was 12.2 months. The 1- and 2-year survival rates were 44% and 27%, respectively. However, this regimen was also associated with significant toxicities, including grade 3 or higher leukopenia (21%), neutropenia (33%), anemia (25%), and thrombocytopenia (20%).¹⁶¹ A phase III randomized trial found irinotecan and gemcitabine to be an effective regimen in the first-line treatment of patients with CUP, with a response rate and 2-year survival rate of 18% each. Median PFS and OS were 5.3 months and 8.5 months, respectively.¹³² The Panel recommends irinotecan and carboplatin as a treatment option for occult primary adenocarcinoma; irinotecan and gemcitabine should be reserved for patients who are ineligible to receive platinum-based chemotherapy.

NCCN Guidelines Version 2.2025

Occult Primary

Capecitabine or Fluorouracil

Capecitabine and fluorouracil are commonly used as single agents in the treatment of GI cancers.¹⁶²⁻¹⁶⁵ A trial conducted by the National Surgical Adjuvant Breast and Bowel Project reported that treatment with fluorouracil significantly improved disease-free survival (DFS) and OS in patients with stage II or III colon cancer.¹⁶⁴ In this trial, 1081 patients were randomized to receive fluorouracil or lomustine, vincristine, and fluorouracil (MOF). Three-year DFS was 73% in the fluorouracil group compared to 64% in patients receiving MOF ($P = .003$). Additionally, patients treated with fluorouracil had a 30% reduction in treatment failure and a 32% reduction in mortality risk compared to patients treated with MOF after 3 years of follow-up. In a phase III randomized trial involving 1987 patients with metastatic colon cancer, adjuvant treatment with single-agent capecitabine improved relapse-free survival (HR, 0.86; 95% CI, 0.74–0.99; $P = .04$) and was associated with significantly fewer adverse events than fluorouracil ($P < .001$).¹⁶² Therefore, single-agent capecitabine and single-agent fluorouracil are recommended options for the treatment of occult primary adenocarcinoma. Single-agent capecitabine or fluorouracil can be given with concurrent RT, if clinically indicated.

Fluorouracil/Leucovorin, Irinotecan, and Oxaliplatin (FOLFIRINOX) and mFOLFIRINOX

The FOLFIRINOX regimen is commonly used in the treatment of pancreatic cancer.¹⁶⁶⁻¹⁷⁰ The landmark phase III PRODIGE trial, which randomized 342 patients with metastatic pancreatic cancer and good PS to receive FOLFIRINOX or gemcitabine, found that treatment with FOLFIRINOX resulted in dramatic improvements in median OS (11.1 vs. 6.8 months; $P < .001$), median PFS (6.4 vs. 3.3 months; $P < .001$), and ORR (31.6% vs. 9.4%; $P < .001$) compared to treatment with gemcitabine.¹⁶⁶ In a systematic review and meta-analysis that included 315 patients with locally advanced pancreatic cancer across 11 studies,

treatment with FOLFIRINOX showed a pooled median OS of 24.2 months, which is longer than that typically observed with gemcitabine (6–13 months).¹⁶⁹ However, FOLFIRINOX has been associated with significant toxicities, including grade 3–4 febrile neutropenia, thrombocytopenia, diarrhea, vomiting, fatigue, and sensory neuropathy.^{166,169} Additionally, there is a lack of data regarding the efficacy of FOLFIRINOX in the treatment of CUP. Therefore, FOLFIRINOX should be reserved for patients with a PS of 0–1 and a presumed GI primary site.

The mFOLFIRINOX regimen has also shown efficacy in the treatment of pancreatic adenocarcinoma. In a multicenter phase III trial, 493 patients with resected pancreatic ductal adenocarcinoma were randomized to receive mFOLFIRINOX or gemcitabine.¹⁷¹ At a median follow-up of 34 months, the median DFS was 22 months in the mFOLFIRINOX group and 13 months in the gemcitabine group ($P < .001$). The median OS was 54 months with mFOLFIRINOX compared to 35 months with gemcitabine ($P = .003$). The 3-year OS rate was 63% in the modified-FOLFIRINOX group and 49% in the gemcitabine group. Grade 3 or 4 adverse events occurred in 76% of patients receiving mFOLFIRINOX compared to 53% of those receiving gemcitabine. Due to significant toxicity and a lack of data regarding the efficacy of mFOLFIRINOX in the treatment of CUP, mFOLFIRINOX should be reserved for patients with a PS of 0–1 and a presumed GI primary site.

Pembrolizumab

Pembrolizumab, an anti-programmed cell death protein 1 (PD-1) antibody, was approved by the FDA in 2017 for the treatment of patients with unresectable or metastatic MSI-H/dMMR solid tumors that have progressed following prior treatment and who have no satisfactory alternative treatment options.¹⁷² This first-ever tissue- and site-agnostic approval was based on data from 149 patients with MSI-H/dMMR cancers

NCCN Guidelines Version 2.2025

Occult Primary

(90 patients had colorectal cancer) enrolled across five multicenter single-arm clinical trials. One of the trials included in the FDA approval was KEYNOTE-016, a phase II trial that evaluated the activity of pembrolizumab in 41 patients with metastatic treatment-refractory dMMR colorectal cancer, MMR-proficient colorectal cancer, or dMMR non-colorectal cancer who had received at least two previous lines of therapy.^{173,174} The immune-related ORR for patients with dMMR colorectal cancers was 40% with an immune-related PFS rate of 78%.¹⁷³ Responses of patients with dMMR noncolorectal cancers were similar. Importantly, the immune-related ORR and PFS rate were 0% and 11%, respectively, in patients with MMR-proficient colorectal cancer. In an expansion of this study, data from 86 patients with dMMR tumors representing 12 different cancer types achieved an ORR of 53% with 21% of patients achieving a complete response to pembrolizumab.¹⁷⁴ In the phase II KEYNOTE-158 trial, 233 patients with 27 different MSI-H/dMMR tumor types (endometrial, gastric, cholangiosarcoma, and pancreatic cancers being the most common) were treated with pembrolizumab following the failure of at least one previous line of therapy.¹⁷⁵ After a median follow-up of 13 months, the ORR was 34.3%. Median PFS was 4 months and median OS was 24 months. Treatment-related adverse events occurred in 64.8% of patients (14.6% were grade 3–5).

In 2020, the FDA approved pembrolizumab for the treatment of patients with metastatic TMB-high (TMB-H) [≥10 mutations/megabase (mut/Mb)] solid tumors, as determined by an FDA-approved test, that have progressed following prior treatment and who have no satisfactory alternative treatment options.¹⁷⁶ This approval was based on a retrospective analysis of 102 patients enrolled in the KEYNOTE-158 trial who had tumors identified as TMB-H.¹⁷⁷ The ORR for these patients was 29%, with a 4% complete response rate and 25% partial response rate. The median duration of response was not reached, with 50% of patients having response durations for ≥24 months. Based on these data,

pembrolizumab may be used to treat patients with MSI-H/dMMR or TMB-H (≥10 mut/Mb) occult primary tumors.

Dostarlimab-gxly

Dostarlimab-gxly, an anti-PD-1 antibody, was approved by the FDA in 2021 for the treatment of patients with dMMR recurrent or advanced solid tumors that have progressed on or following prior treatment and who have no satisfactory alternative treatment options.¹⁷⁸ This approval was based on data from the nonrandomized phase 1 multi-cohort GARNET trial that evaluated the safety and antitumor activity of dostarlimab-gxly in 209 patients with dMMR solid tumors.^{179,180} The majority of patients had endometrial or GI cancers. The ORR was 42%, with a 9% complete response rate and 33% partial response rate, and the median duration of response was 35 months. The most common treatment-related adverse events were fatigue, anemia, diarrhea, and nausea. Immune-mediated adverse events also occurred, including pneumonitis, colitis, hepatitis, endocrinopathies, nephritis, and dermatologic toxicities. Based on these data, dostarlimab-gxly may be used to treat patients with MSI-H/dMMR occult primary adenocarcinoma tumors.

Selpercatinib

Selpercatinib, a *RET* kinase inhibitor, was approved by the FDA in 2022 for the treatment of advanced or metastatic *RET* gene fusion-positive solid tumors that have progressed on or following prior systemic treatment or who have no satisfactory alternative treatment options.¹⁸¹ This approval was based on data from the ongoing international phase I/II LIBRETTO-001 trial, which evaluated the dose escalation and dose expansion of selpercatinib in patients with *RET* gene fusion-positive tumors (other than non-small cell lung cancer and thyroid cancer).¹⁸² The ORR was 44% in the 41 evaluable patients who received the recommended starting dose of 160 mg twice daily. Serious treatment-

NCCN Guidelines Version 2.2025

Occult Primary

related adverse events occurred in 40% of 45 patients. The most common grade 3 or higher treatment-related adverse events were hypertension (22%), increased alanine aminotransferase (16%), and increased aspartate aminotransferase (13%). Based on these data, selpercatinib may be used to treat patients with locally advanced or metastatic solid tumors that progressed on or following prior systemic treatment or who have no satisfactory alternative treatment options.

Dabrafenib and Trametinib

Dabrafenib, a *BRAF* V600E-directed tyrosine kinase inhibitor (TKI), used in combination with trametinib, a MEK inhibitor, was approved by the FDA in 2022 for the treatment of unresectable or metastatic *BRAF* V600E mutated solid tumors that have progressed following prior treatment and have no satisfactory alternative treatment options.¹⁸³ The open-label, single-arm EAY131-H study evaluated the efficacy of dabrafenib and trametinib in solid tumors with *BRAF* V600 mutations (excluding those with melanoma, thyroid or colorectal cancer, and non-small cell lung cancer).¹⁸⁴ Of the 29 patients included in the primary efficacy analysis, ORR was 38% (90% CI, 22.9%–54.9%) with $P < .0001$ against a null rate of 5%, and PFS was 11.4 months (90% CI, 8.4–16.3 months). Average OS was 28.6 months. Based on these data, the Panel recommends dabrafenib and trametinib as a treatment option for patients with *BRAF* V600E mutated solid tumors that have progressed following prior treatment and have no satisfactory treatment options.

Entrectinib, Larotrectinib, and Repotrectinib

Entrectinib and larotrectinib (*TRK*-directed TKIs), and repotrectinib (a next-generation *ROS1* and *TRK*-directed TKI), are used as single agents in patients with *NTRK* gene fusion-positive tumors without a known acquired resistance mutation, that are metastatic or where surgical resection is likely to result in severe morbidity, and that have no satisfactory alternative

treatments or that have progressed following treatment. A pooled analysis of three clinical trials (two phase 1 trials [ALKA-372–001 and STARTRK-1] and one phase 2 trial [STARTRK-2]) evaluated the activity of entrectinib in 54 patients aged ≥ 18 years with *NTRK* gene fusion-positive solid tumors.⁴⁵ Thirty one participants (57%; 95% CI 43.2–70.8]) had an objective response, of which 4 (7%) and 27 (50%) had a complete response and partial response, respectively. The average duration of response was 10 months. To evaluate the efficacy of larotrectinib on *NTRK* gene fusion-positive solid tumors, 55 patients were enrolled in one of three protocols: a phase 1 study involving adults, a phase 1–2 study involving children, or a phase 2 study involving adolescents and adults.⁴⁴ ORR was 75% (95% CI, 61–85) at the primary data cutoff date. Seven (13%) patients had a complete response, 34 (62%) had a partial response, and 7 (13%) had stable disease. At 1 year, 71% of participants continued to have a response and 55% remained progression free. The ongoing phase I/II TRIDENT-1 trial evaluated the safety and efficacy of repotrectinib in TKI-naïve and TKI-pretreated *ROS1* and *NTRK* gene fusion-positive locally advanced or metastatic solid tumors.¹⁸⁵ Of the total participants in the study (TKI-naïve: $n = 40$; TKI-pretreated: $n = 48$), one ($n = 1$) had CUP in the TKI-pretreated cohort. The primary endpoint of TRIDENT-1 was confirmed ORR and results showed an ORR of 50% (95% CI, 35–65) in the TKI-pretreated cohort (Clinical Trial ID: NCT03093116).

Fam-Trastuzumab Deruxtecan-nxki

Fam-trastuzumab deruxtecan-nxki (T-DXd), an antibody drug conjugate, was approved by the FDA in 2024 for patients with HER2-positive (IHC 3+) advanced or metastatic solid tumors that progressed on or following prior systemic treatment and who have no satisfactory alternative treatment options.¹⁸⁶ An open-label phase II study evaluated the efficacy of T-DXd in 267 patients (of which $n = 5$ had CUP) with HER2-expressing (IHC 3+/2+) locally advanced or metastatic solid tumors who had received ≥ 1 systemic treatment or without alternative treatment options.¹⁸⁷ Results

NCCN Guidelines Version 2.2025

Occult Primary

in those with central HER2 (IHC 3+) expressing solid tumors showed an ORR of 61.3% (95% CI, 49.4–72.4) and average OS of 21.1 months (95% CI, 15.3–29.6). Based on these data, the Panel recommends T-DXd as a useful in certain circumstances treatment option for patients with HER2-positive (IHC 3+) solid tumors who meet the criteria consistent with the FDA indication.

Squamous Cell Carcinoma

Platinum-based regimens have typically been used to treat disseminated SCC. Historically, the combination of cisplatin and fluorouracil has been the most frequently used regimen for patients with SCC of unknown primary.^{188,189} Overall, only a few small studies have evaluated the efficacy of systemic therapy regimens in patients with SCC occult primary tumors. Therefore, the Panel lists possible regimens based on evidence from studies of patients with SCC of known primaries and small studies of patients with SCC of occult primaries. Regimens other than those listed can also be considered.

Paclitaxel and Carboplatin

In the Hellenic Cooperative Oncology Group phase II study of paclitaxel and carboplatin in patients with CUP (discussed above for adenocarcinoma), three patients had tumors of SCC histology.¹²⁹ These patients had a response rate of 30% and a median response duration of 3 months. The Panel recommends paclitaxel and carboplatin as a preferred treatment option for patients with occult primary SCC.

mFOLFOX6

FOLFOX is used to treat SCC of the esophagus and stomach.^{190,191} The Panel lists mFOLFOX6 as a preferred treatment option for occult primary SCC based on the evidence discussed above for adenocarcinoma.^{147,148}

Gemcitabine and Cisplatin

The GEFCAPI 02 trial compared cisplatin to cisplatin plus gemcitabine in 52 patients with CUP.¹³⁹ Although the trial was terminated early due to poor accrual, there was a trend towards better OS with the addition of gemcitabine (11 vs. 8 months, with overlapping CIs).

Capecitabine or Fluorouracil

As previously stated, capecitabine and fluorouracil are commonly used as single agents in the treatment of GI cancers.¹⁶²⁻¹⁶⁵ The Panel lists single-agent capecitabine and single-agent fluorouracil as treatment options for occult primary SCC based on the evidence discussed above for adenocarcinoma. Single-agent capecitabine or fluorouracil can be given with concurrent RT, if clinically indicated.

Paclitaxel and Cisplatin

The combination of paclitaxel and cisplatin is commonly used to treat esophageal, head and neck, and non-small cell lung cancers.^{125,192-195}

This regimen has also been assessed in a phase II study of 37 patients with unfavorable presentations of CUP.¹⁹⁶ The ORR was 42% (95% CI, 23%–61%), median time to disease progression was 4 months (95% CI, 1.3–6.8), and the median OS was 11 months (95% CI, 8.3–13.5). Three of the 37 patients had SCC.

Docetaxel and Carboplatin or Cisplatin

The combination of docetaxel and carboplatin was assessed in a phase II trial of 47 patients with CUP.¹⁵⁹ Twenty-four patients had favorable risk disease (defined as predominantly nodal disease or non-mucinous peritoneal carcinomatosis) and 23 had unfavorable risk disease (visceral metastases). The average response rate was 32%, the median time to disease progression was 5.5 months, and the median OS was 16.2 months. It is important to note that these results were mainly driven by

NCCN Guidelines Version 2.2025

Occult Primary

the superior outcomes seen in patients with favorable risk disease. Patients with favorable risk disease had a response rate of 46% (compared to 17% in patients with unfavorable risk disease) and a median OS of 22.6 months (compared to only 5.3 months in patients with unfavorable risk disease).

The efficacy of docetaxel and cisplatin was assessed in a trial of 45 patients with CUP.¹⁹⁷ The ORR was 65.1%, the median time to progression was 5 months, and the median OS was 11.8 months. Two patients in this study had tumors of SCC histology and both had a partial response to the docetaxel/cisplatin regimen. Combination therapy with docetaxel and cisplatin was also examined in a cohort of 29 patients with CUP, four of whom had tumors of SCC histology.¹⁶⁰ The ORR was 37.9%, and median PFS and OS were 6 months and 16 months, respectively.

Cisplatin and Fluorouracil

This regimen has historically been used in the treatment of metastatic anal, head and neck, and esophageal SCC.^{194,198-202} Cisplatin and fluorouracil has been retrospectively evaluated in patients with SCC of unknown primary.^{188,189} Kusaba et al reported a response rate of 54.5%, median time to progression of 3 months, and a median OS of 10 months in a retrospective analysis of 11 patients with CUP who had received this regimen.²⁰³ Combined cisplatin and fluorouracil can be given with concurrent RT, if clinically indicated.

Docetaxel, Cisplatin, and Fluorouracil (DCF)

The combination of docetaxel, cisplatin, and fluorouracil is commonly used to treat gastric, esophageal, and head and neck cancers.²⁰⁴⁻²⁰⁷ In a randomized trial of 213 patients with advanced SCC of the head and neck, patients received cisplatin and fluorouracil (with or without docetaxel) followed by RT.²⁰⁴ The ORRs were 80% and 59.2% in the 3-

drug and 2-drug arms, respectively ($P = .002$). A similar trial involving 501 patients with advanced head and neck SCC reported ORRs of 72% and 64%, respectively, for patients treated with DCF or cisplatin and fluorouracil alone.²⁰⁵ However, DCF has been associated with significant toxicities, including grade 4 febrile neutropenia, and should therefore be reserved for patients with a PS of 0 to 1.

Pembrolizumab

The Panel recommends pembrolizumab for dMMR/MSI-H or TMB-H (≥ 10 mut/Mb) occult primary SCC tumors based on the evidence discussed above for adenocarcinoma.^{175,177}

Selpercatinib

The Panel recommends selpercatinib for patients with locally advanced or metastatic solid SCC occult primary tumors that progressed on or following prior systemic treatment or who have no satisfactory alternative treatment options based on the evidence discussed above for adenocarcinoma.¹⁸²

Neuroendocrine Tumors

Neuroendocrine CUPs are uncommon, constituting approximately 12% to 22% of all diagnosed neuroendocrine tumors, and their clinical behavior is dependent on the tumor grade and level of differentiation.^{208,209} Neuroendocrine tumors, regardless of grade, represent a favorable prognostic subset of CUPs that are responsive to combination chemotherapy, making long-term survival a possibility in some patients.²⁰⁸

Hainsworth et al evaluated the efficacy of paclitaxel, carboplatin, and etoposide in patients with metastatic PDNE carcinomas who had received no prior treatment.²¹⁰ Of these patients, 62% had PDNE of unknown primary. Major responses were observed in 53% of patients,

NCCN Guidelines Version 2.2025

Occult Primary

with a median survival of 14.5 months and 2- and 3-year survival rates of 33% and 24%, respectively. The results of this trial showed that PDNE carcinomas are chemosensitive, with a high ORR to combination chemotherapy.

In another study, the combination of cisplatin and etoposide produced significant responses in patients with poorly differentiated, rapidly progressing neuroendocrine tumors (carcinoids and pancreatic neuroendocrine tumors of known primaries) when used as a second- or third-line treatment.²¹¹ In two small series of patients, temozolomide, as a single agent or in combination with thalidomide, was also found to be effective in the treatment of advanced or metastatic neuroendocrine tumors.^{212,213}

PDNE tumors can also be treated with small cell lung cancer regimens. In a randomized phase III trial (JCOG 9702), the combination of carboplatin plus etoposide was equally as effective as cisplatin plus etoposide in older patients with small cell lung cancer or those with poor-risk disease who were not previously treated.²¹⁴ No significant differences were seen in response rate (73% for both regimens) and median OS (10.6 months for carboplatin and etoposide vs. 9.9 months for cisplatin and etoposide).

The Panel recommends that poorly differentiated (high-grade or anaplastic) or small cell subtype (other than lung) neuroendocrine tumors be treated following the [NCCN Guidelines for Small Cell Lung Cancer](#). Well-differentiated neuroendocrine tumors should be treated as carcinoid tumors in the [NCCN Guidelines for Neuroendocrine and Adrenal Tumors](#).

Leucovorin Shortage

Leucovorin is indicated with certain fluorouracil-based regimens. However, there is currently a shortage of leucovorin in the United States.¹⁷² There are no specific data to guide management under these circumstances,

and all proposed strategies are empiric. One is the use of levoleucovorin, which is commonly used in Europe. A levoleucovorin dose of 200 mg/m² is equivalent to 400 mg/m² of standard leucovorin. Another option is to use lower doses of leucovorin in all patients, since lower doses are likely to be as efficacious as higher doses based on several studies in patients with colorectal cancer.²¹⁵⁻²¹⁷ However, there are insufficient high-quality data to support either approach. Therefore, the Panel recommends use of these regimens without leucovorin in situations where leucovorin is not available.

Radiation Therapy

RT is a treatment option for a variety of localized tumors, particularly as follow-up treatment after lymph node dissection. Adjuvant RT may be appropriate if the disease is limited to a single nodal site with extranodal extension, or in the case of inadequate nodal dissection with multiple positive nodes. Definitive RT can be considered for patients with localized disease. RT alone may also be considered for bone lesions, a retroperitoneal mass with non-germ cell histology, or supraclavicular nodal involvement in site-specific SCC. Stereotactic ablative radiotherapy (SABR) may be used for limited (1–3) metastases or pulmonary metastases.^{218,219} In the palliative setting, hypofractionated RT can be considered for symptomatic patients with uncontrolled pain, impending pathologic fracture, or impending spinal cord compression.

A study by Janssen et al examined individualized intensity-modulated RT (IMRT) with risk-adapted planning treatment volumes in 28 patients with CUP and cervical nodal metastases.²²⁰ The majority of patients (71%) received concomitant systemic therapy. In this cohort, 3-year OS, mucosal control, neck control, and distant metastasis-free survival rates were 76%, 100%, 93%, and 88%, respectively. No patient experienced a locoregional recurrence and no grade 2 or higher adverse events were reported. Another retrospective study evaluated the utility of IMRT in 260 patients with CUP metastatic to the neck. The 5-year OS, regional

NCCN Guidelines Version 2.2025

Occult Primary

control, and distant metastases-free survival rates were 84%, 91%, and 94%, respectively.²²¹ However, 7% of patients were diagnosed with chronic radiation-associated dysphagia. A third retrospective study assessed RT in 68 patients with metastatic head and neck SCC of unknown primary.²²² These patients underwent oropharynx-targeted RT to spare the mucosal surfaces of the nasopharynx, hypopharynx, and larynx; 40% of patients received IMRT and 56% of patients received concurrent chemoradiation, resulting in an actuarial locoregional control rate of 95.5% and a median time to locoregional recurrence of 18 months. RT-associated toxicities included grade 1 xerostomia, dysphagia, neck stiffness, and trismus. The results of these studies are promising; however, large randomized prospective trials are needed to further assess the efficacy and safety of IMRT-based treatment approaches for CUP.

Locoregional Therapeutic Options

In patients with unresectable localized liver lesions, locoregional therapeutic options may be considered when clinically indicated based on tumor size, pathology, and clinical presentation. Recommendations for locoregional treatment options are described in the [NCCN Guidelines for Hepatocellular Carcinoma](#).

Specialized Approaches

Specialized approaches are suggested for all patients with disseminated metastases. The term emphasizes the importance of individualized treatment plans. Specialized approaches may include palliative care options (such as thoracentesis and paracentesis), targeted therapies, and/or novel approaches to RT. The importance of distress management is also discussed in the algorithm and included as a specialized approach. For many patients the apparent uncertainties surrounding the diagnosis of an unknown primary cancer may result in significant psychosocial distress

and increased difficulty in accepting treatment options. Empathetic discussion about the natural history of these types of cancer and their prognosis, and the provision of support and counseling both by the primary oncology team and specialized services may help to alleviate this distress. For additional information on addressing psychosocial distress, see the [NCCN Guidelines for Distress Management](#).

Follow-up

Follow-up frequency should be determined by clinical need in patients with active disease or localized disease in remission. Follow-up consists of a history and physical examination, with diagnostic tests for patients who are symptomatic.

For patients with active and incurable disease, psychosocial support, symptom management, end-of-life discussions, palliative care interventions, and hospice care should all be considered and used as appropriate (see *Psychosocial Distress* and *Supportive Care* above). Please see the [NCCN Guidelines for Distress Management](#), the [NCCN Guidelines for Palliative Care](#), and the [NCCN Guidelines for Survivorship](#) for more information.
